FOREWORD

The research reported here was conducted at Arnold Engineering Development Center (AEDC), Air Force Systems Command (AFSC), and was carried out under sponsorship of the USAF Aerospace Research Laboratories, Wright-Patterson AFB, Ohio, under Program Element 65802F.

The results of this research program were obtained by ARO, Inc. (a subsidiary of Sverdrup & Parcel and Associates, Inc.), contract operator of AEDC, AFSC, Arnold Air Force Station, Tennessee. The experiments were performed in Propulsion Research Area (R-2E) of the Engine Test Facility (ETF) under ARO Project number RW5211, and the manuscript was submitted for publication on August 16, 1973.

The authors extend acknowledgement to Mr. Bryan L. Seiber, ARO, Inc., Propulsion Wind Tunnel (PWT), and to Dr. Arthur A. Mason, The University of Tennessee Space Institute (UTSI), for helpful discussions which contributed materially to this work, and to Mr. Howard Glassman, who wrote the computer code for simulation of the spectra.

This technical report has been reviewed and is approved.

ABSTRACT

The details of the derivation of working equations for the determination of the concentration of nitric oxide for measurement of the absorption of individual spectral lines lying between 2270 and 2260 Å in the NO (0,0) γ -band are presented. It is shown experimentally that the derivation is accurate, that published values of oscillator strengths are adequate, and that measurements of number densities with uncertainty no greater than ± 20 percent are possible when proper corrections for the relative line widths of source and absorber are made. The density range of use of the (0,0) γ -band is from about 10^{14} to 10^{16} cm⁻³ for path lengths usually encountered in combustion system testing (10 to 100 cm). Extension of the range to larger concentrations by use of the (0,1) γ -band and the application to media having nonuniform concentration and temperature are discussed.

SECTION I

A large effort is currently being put forth to measure the contribution to atmospheric pollution of nitric oxide (NO) for automobile and jet engine exhausts. Techniques used to measure NO concentrations have generally been hindered by (1) the small concentrations which are encountered in pollution sources (on the order of 100 parts per million), and (2) the tendency of NO to chemically combine with other compounds in sample cells and hence reduce the actual concentration in the sample measured. No completely satisfactory method has been developed to measure NO concentrations. Reported herein are the results of an investigation of the feasibility of a nonsampling, in situ, ultraviolet absorption method to measure NO concentrations.

The specific purpose of the work reported herein was to develope a technique to determine concentrations of NO from measurement of the absorption of spectral lines lying in the ultraviolet γ -bands of NO. The narrow line absorption technique has been in use for many years but application to the NO molecule has not been made, principally because of the inability of ordinary spectrometric equipment to completely resolve the rotational lines in the NO γ -bands. A lucid explanation of the spectral line absorption technique is contained in the book by Mitchel and Zemansky (Ref. 1) but certain adjustments must be made in order to apply the technique to the NO molecule. The development of the theory of absorption of spectral lines will be systematically made in this report for the sake of clarity, although portions of the treatment appear throughout the literature. Other research programs at AEDC (Refs. 2 and 3) have made use of the narrow line absorption method for determination of hydroxyl (OH) concentrations in flames, but the treatment of the equations for OH is not quite the same as for NO because of the different molecular structure and line broadening properties. Tabulations of the structural properties of the NO molecule are also scattered in the literature, and these data will also be assembled in a systematic manner in this report. Finally, a numerical working equation for determination of NO concentration from measured spectral line transmission will be developed.

In the experimental work, a high-intensity, narrow-line source of NO radiation was developed. Parallel light emanating from the source was passed through a cylindrical absorption cell containing NO at a known partial pressure. The length of the absorption cell was

accurately known, and the diameter of the beam of parallel light passing through the cell was smaller than the diameter of the absorption cell. The concentration of NO as determined from measurements of the temperature and pressure in the absorption cell was compared with the results of the absorption measurement. The results of the comparison were satisfactory, considering the uncertainties in the theory and the measurements. Finally, some implied conclusions about the method, the development of the theory, and applications are discussed.

SECTION II THEORY OF THE METHOD

2.1 DESCRIPTION OF THE MEASUREMENT PROCEDURE

The basic principle upon which the measurement technique being described here exists is that a beam of light is absorbed by the gas at some determinable wavelength, and that the magnitude of the absorption is uniquely related to the concentration and temperature of the absorbing species along the path length. The measurement required is the absorptivity

$$a_{\nu} = \left[(I^{\circ} - I_{m})/I^{\circ} \right]_{\nu}$$

or transmissivity

$$t_{\nu} = [I_{m}/I^{o}]_{\nu}$$

within a given wave number interval ($\Delta\nu$) where I^O is the incident intensity and I_m is the transmitted intensity as illustrated in Fig. 1. The problem is to relate this measurement to the properties (concentration of absorbing species, temperature, and pressure) of the absorbing medium. This section is devoted to a systematic derivation of the relationship between the measured transmission and the concentration and temperature of the NO molecule and the pressure of the absorbing medium.

The (0,0) band of the ultraviolet resonance γ -system of NO was chosen for the measurements. The first band-head of the (0,0) band is at 2269.4 Å. NO has an infrared absorption spectrum at about 5.2 microns, but this region of the spectrum is cluttered with band systems of other molecules such as CO and several minor components of

combustion gases. The 2269 Å region does not suffer from overlapping of other bands.

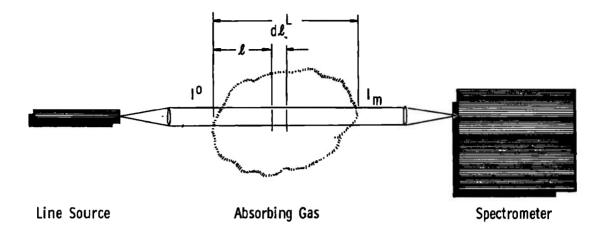

Fig. 1 Physical Arrangement for Spectral Line Absorption Measurements

2.2 DEFINITION OF THE ABSORPTION COEFFICIENT

If radiation from a continuum source is directed through a gas as shown in Fig. 1, the transmitted beam will suffer absorption at selected wave numbers appropriate to the gas species. The absorption coefficient (k_{ν}) of the gas at some appropriate wave number (ν) is defined by the equation (Ref. 1):

$$\frac{\mathrm{d}I_{\nu}}{\mathrm{d}\ell} = -k_{\nu}I_{\nu} \tag{1}$$

where I_{ν} is the intensity of a beam of light of wave number (ν) at a distance (ℓ) into the gas, and dI_{ν} is the decrease in intensity after passing through a thickness ($d\ell$) of the gas. If the gas has uniform properties, then k_{ν} will be independent of the position and Eq. (1) may be integrated to give

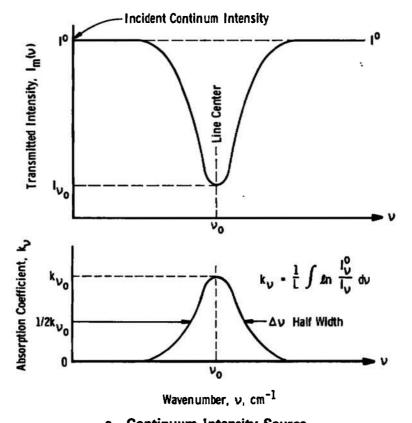

$$\frac{I_{\nu}}{I_{\nu}^{0}} = \exp\left(-k_{\nu}L\right) \tag{2}$$

where I_{ν}^{O} is the incident intensity at wave number (ν) at the entrance to the absorbing layer of thickness (L). If the properties are not uniform,

then

$$\frac{l_{\nu}}{l_{\nu}^{o}} = \exp\left(-\int k_{\nu} d\ell\right) \tag{3}$$

For a real gas, the absorption coefficient of an absorption line is a function of the frequency or wave number; that is, the envelope of the transmission $((I/I^O)_{\nu})$ and the absorption coefficient (k_{ν}) of a continuum source will have the approximate shapes shown in Fig. 2a. The total width of the absorption coefficient curve at the frequency where k_{ν} has fallen to one-half of k_{ν_O} , its maximum value, is called the half-width of the absorption line and is denoted as $\Delta \nu$. In general, the absorption coefficient of a gas is given by an expression involving a function of ν and a definite value of k_{ν_O} and $\Delta \nu$, both of which are functions of the local gas pressure and temperature.

a. Continuum Intensity Source
Fig. 2 Transmitted Intensity and Absorption Coefficient in an Absorbing Gas

In most practical cases in the ultraviolet portion of the spectrum, $\Delta \nu$ is much smaller than the band-pass of the instruments that must be used, so that it is the integral over frequency that is measured:

$$I_{m} = \int_{0}^{\infty} I_{\nu}^{o} \exp\left(-k_{\nu} L\right) d\nu \tag{4}$$

If the source is a continuum, then I_{ν_0} is a constant and may be removed from the integral:

$$I_{m} = I^{o} \int_{2\Delta \nu} \exp(-k_{\nu} L) d\nu$$
 (5)

and the transmission $(t_m = (I_m/I^0))$ is a measure of the absorption integral.

Now, suppose the source is not a continuum but a line at the same frequency as the absorption line but much narrower, as illustrated in Fig. 2b. Then, absorption takes place only over the extent of the incident radiation:

$$I_{m} = \int_{2\Delta \nu} I_{\nu}^{o} \exp(-k_{\nu} L) d\nu$$
 (6)

But now k_{ν} is just the absorption at line center (k_{ν}) and is constant over the integral:

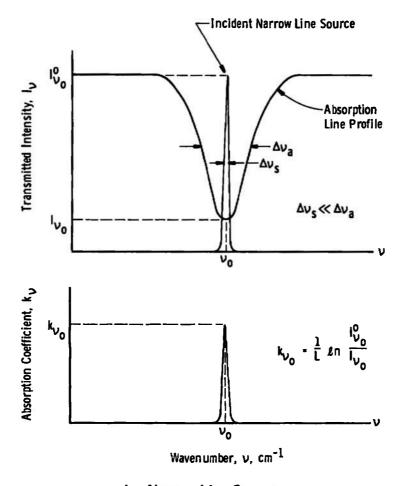

$$I_{m} = \exp(-k_{\nu_{0}}L) \int_{2\Delta\nu} I_{\nu}^{o} d\nu = I_{\nu_{0}}^{o} \exp(-k_{\nu_{0}}L)$$
 (7)

This latter expression is much simpler than Eq. (5) and does not depend on the line shape. This is the essence of the narrow line absorption technique. Furthermore, the measured transmission $(t_m = I_m/I_{\nu_0}^o)$ is a sensitive function of k_{ν_0} .

Suppose that the incident line is not much narrower than the absorption line. The measured transmission is not now a simple function of the absorption coefficient as in the cases defined by Eqs. (5) and (7). Rather, the relationship becomes

$$t_{m} = \frac{I_{m}}{I_{m}^{o}} = \frac{\int I_{\nu} d\nu}{\int I_{\nu}^{o} d\nu} = \frac{\int I_{\nu}^{o} \exp(-k_{\nu} L) d\nu}{\int I_{\nu}^{o} d\nu}$$
(8)

involving the details of the incident source variation with wave number and the absorption line shape. This is the more general line absorption problem and, although much more difficult because of the integration problems, is still much more sensitive to a change in k_{ν} than the continuum expression (Eq. (5)).

b. Narrow Line Source Fig. 2 Concluded

The problem is, then, to determine means by which the measured transmission may be related to the properties of the gas, which are expressible through $\int k_{\nu} d\nu$. In the following sections, the relationship between $\int k_{\nu} d\nu$ and the gas temperature, pressure, and concentration of the absorbing species will be developed, and by examination of the details of the function (k_{ν}) means will be found to extract $\int k_{\nu} d\nu$ from the measured transmission.

2.3 EINSTEIN EQUATION FOR RADIATION

First, consider the situation in which an enclosure contains isotropic radiation of wave number between ν and ν + $d\nu$, intensity I_{ν} , and molecules capable of being raised by absorption of the radiation from the rotational state J'' of one-electronic-vibrational level to the state J' of some higher electronic-vibrational level. The Einstein radiation law relates the rate of photon production from a unit volume of gas for a given transition, to the properties of the gas (Ref. 1); that is, the rate of photon production is equal to

$$A_{J'J''N_{J'}} + B_{J'J''} \frac{l_{\nu}}{4\pi} N_{J'} - B_{J''J'} \frac{l_{\nu}}{4\pi} N_{J''}$$
 (9)

where the Einstein transition probabilities are defined by Milne as described in Ref. 1 in terms of intensity as follows:

- 1. $B_{J''J'}I_{\nu}$ = probability per second that the molecule in state J'' exposed to isotropic radiation of wave number between ν and ν + $d\nu$ and intensity, I_{ν} , will absorb a quantum $hc\nu$ and pass to the state J'. (h is Planck's constant and c is the velocity of light.)
- 2. A J'J'' = probability per second that the molecule in state J' will spontaneously emit a quantum $hc\nu$ and pass to the state J''.
- 3. $B_{J'J''}I_{\nu}$ = probability per second that the molecule will undergo the transition from J´ to J´ when it is exposed to isotropic radiation of wave number between ν and $\nu + d\nu$ and intensity, I_{ν} , and emit a quantum $hc\nu$.

The Einstein transition probabilities as used in Eq. (9) are related by the following equations (Ref. 1):

$$\frac{^{A}J'J''}{^{B}J''J'} = 2 h c \nu^{3} \frac{^{g}J''}{^{g}J'}$$
 (10)

$$\frac{B_{J'J''}}{B_{J''J'}} = \frac{g_{J''}}{g_{J'}} \tag{11}$$

where g_{J} and g_{J} are the statistical weights of the lower and upper excited states, respectively.

Consider a parallel beam of light of wave number between ν and ν + d ν and traveling in the positive direction through a layer of molecules bounded by the planes at ℓ and ℓ + d ℓ (Fig. 1). Suppose there are N_J molecules per cubic centimeter in the J state of which δ N_{ν J} are capable of absorbing in the range between ν and ν + $\delta\nu$, and N_J excited molecules per cubic centimeter in the J state of which δ N_{ν J} are capable of emitting in this wave number interval. Assuming that the incident intensity is much greater than the spontaneous emission, the first term on the right of Eq. (9) can be neglected and the decrease in intensity of the incident beam along the path is given by

$$-d[I_{\nu}\delta_{\nu}] = \delta N_{\nu J} h_{\nu}B_{J} d\nu - \delta N_{\nu J} h_{\nu}B_{J} d\nu - \delta N_{\nu J} d\nu$$
(12)

where $I_{\nu}/4\pi$ is the intensity of the equivalent isotropic radiation for which $B_{J}''J'$ and $B_{J}'J''$ are defined. Rewriting Eq. (12) gives

$$-\frac{1}{I_{\nu}}\frac{dI_{\nu}}{d\ell}\delta\nu = \frac{h_{\nu}}{4\pi}\left(B_{J}_{J}^{\prime\prime}\delta N_{\nu J}^{\prime\prime} - B_{J}_{J}^{\prime\prime}\delta N_{\nu J}^{\prime\prime}\right)$$
(13)

By recognizing that the left hand side of the equation is $k_{\nu}\delta\nu$ with k_{ν} as defined by Eq. (1), Eq. (13) becomes

$$k_{\nu}\delta\nu = \frac{h_{\nu}}{4\pi}(B_{J''J'}\delta N_{\nu J''} - B_{J'J''}\delta N_{\nu J'})$$
 (14)

Integrating over the whole absorption line and neglecting the small change in ν throughout the line results in

$$\int k_{\nu} d\nu = \frac{h_{\nu_0}}{4\pi} (B_{J''J'} N_{J''} - B_{J'J''} N_{J'})$$
 (15)

where ν_0 is the wave number at the center of the line. By using Eqs. (10) and (11), Eq. (15) can be rewritten as

$$\int k_{\nu} d\nu = \frac{g_{J}''}{g_{J}'''} \frac{A_{J'J''NJ''}}{8\pi^{c}\nu_{0}^{2}} \left[1 - \frac{g_{J''NJ''}}{g_{J'NJ''}} \right]$$
 (16)

For gases in equilibrium, the Boltzmann distribution holds, and

$$\frac{N}{N} \frac{\text{Upper}}{\text{N}_{J''}} = \frac{g_{J'}}{g_{J''}} \exp\left(\frac{E_{J''} - E_{J'}}{\kappa T}\right)$$
(17)

where E_{J} is the potential energy of the lower electronic vibrational-rotational state, E_{J} is the energy of the upper J' state, κ is Boltzmann's constant, and T is the gas temperature. For the ultraviolet spectral region, E_{J} - E_{J} ~ -40,000 cm⁻¹, κ = 0.695 cm⁻¹/°K, and for the temperatures encountered (300 to 3000°K), the exponential is very small. Thus N_{J} / N_{J} < 10⁻⁷, and the term in parenthesis in Eq. (16) is approximately unity. That is,

$$\int k_{\nu} d\nu = \frac{g_{J}'}{g_{J}''} \frac{N_{J}''^{A}_{J}'_{J}''}{g_{\pi} c_{\nu}^{2}}$$
 (18)

The spontaneous transition probability $(A_{J'J''})$ is related to a term most used in the literature, the oscillator strength, or f-value, through the equation (Ref. 1):

$$\frac{\pi e^2}{mc^2} N_J \sim f_{J'J} \sim = \frac{g_{J'}}{g_{J''}} \frac{N_J \sim A_{J'J''}}{g_{\pi} c_{\nu_0}^2}$$
 (19)

where m is the electron mass and e is the electron charge. Substituting Eq. (19) into Eq. (18) then gives

$$\int k_{\nu} d\nu = \frac{\pi e^2}{m c^2} N_{J} \cdots \widehat{f}_{J' J' \uparrow [N]}$$
(20)

2.4 SPECTRAL LINE SHAPE

Equation (20) expresses the integral of the absorption coefficient in terms of the population density of the lower rotational state of the absorbing gas (N_J ") which is a function of the density of the absorbing species and the temperature, and f_J ', which is a constant of the molecule. However, an explicit expression for k_{ν} or $f_{\nu}^{*} d_{\nu}$ in terms of the measured transmittance or absorption must be obtained in order to use this relationship. An examination of the processes that contribute to the formation of an absorption line of a gas will yield information leading to such an expression.

There are, in general, five processes which contribute to the definition of the shape of an absorption or emission line. Each process can be regarded as an agent for perturbing the energy levels associated with the transition. The result is a broadening of the line. The five processes are:

- 1. Natural broadening, due to the finite lifetime of the excited state.
- 2. Doppler broadening, due to the motions of the molecules.
- 3. Lorentz broadening, due to collisions with foreign gases.
- 4. Holtsmark broadening, due to collisions with other absorbing molecules of the same kind.
- 5. Stark broadening, due to collisions with electrons and ions.

Processes 1 and 5 may be neglected for the temperature range being considered since they contribute much less to the broadening than processes 2, 3, and 4. Processes 3 and 4 have generally been grouped together under the name "pressure" broadening. Thorson and Badger (Ref. 4) have shown that pressure broadening in the bands of NO is much less than Doppler broadening at temperatures greater than room temperature and at pressures less than atmospheric. Therefore, for the work reported here, pressure broadening was neglected and to a very good approximation, Doppler broadening is the only process which contributes to the formation of absorption lines for the NO γ -bands. For the OH molecule, this is not the case, and the combined Doppler and pressure broadening had to be considered (Refs. 2 and 3).

When Doppler broadening is the dominant mechanism the absorption coefficient is given by (Ref. 1):

$$k_{\nu} = k_{\nu_0} \exp \left[-\frac{2(\nu - \nu_0)}{\Delta \nu_D} \sqrt{\ln 2} \right]^2$$
 (21)

where $\Delta \nu_D$ is the Doppler half-width at half of k_{ν_0} , the maximum absorption coefficient, and $\Delta \nu_D$ depends only on the absolute temperature (T), the central wave number (ν_0), and the molecular mass (M) of the absorbing species, according to the relation

$$\Delta \nu_{\rm D} = 2\nu_{\rm o} \frac{\sqrt{2 \kappa T \, \ell_{\rm n2}}}{m \, c^2} \tag{22}$$

Integrating Eq. (21) over ν yields the result

$$\int_{0}^{\infty} k_{\nu} d\nu = \frac{1}{4} \sqrt{\pi/\ln 2} k_{\nu_0} \Delta\nu_D$$
 (23)

Equating the right hand sides of Eqs. (20) and (23) gives

$$\frac{1}{2}\sqrt{\pi/\ln 2} \ k_{\nu_0} \Delta \nu_D = \frac{\pi e^2}{mc^2} N_J " f_{J'J} "$$
 (24)

Now, rewriting Eq. (24) in terms of the absorption coefficient at the line center (k_{ν_0}) , the Doppler width $(\Delta\nu_D)$, and known properties of the molecule results in

$$N_{J''} = \frac{1}{2\sqrt{\pi \ell_{n} 2}} \frac{mc^{2}}{e^{2}} \frac{k_{\nu_{o}} \Delta \nu_{D}}{f_{J'J''}}$$
 (25)

It should be noted at this point that the assumption of a Doppler line shape has imposed a very useful property for the measurement technique. In Eq. (25), N_J. has been simply related to the absorption coefficient at line center (k_{ν 0}) so that some contrivance which enables this measurement to be made is a necessary part of the technique. Then, Eq. (7) is applicable, and k_{ν 0} can easily be determined experimentally.

The measurement can be accomplished if the source in Fig. 1 is composed of lines having the same wavelength as those of the species to be measured, which are very narrow compared with the width of the absorption lines. One way in which this may be accomplished is through use of a resonance lamp containing the species of interest in which the temperature of the source is much less than the temperature of the absorbing medium. Even when the source lines are of comparable width to those of the absorber, the integrals in Eq. (8) can be solved if the incident line shape and the absorption line shape are known. A solution of Eq. (8) for the case of Doppler line shapes is given in Appendix I where it is shown that the measured transmission can be expressed in terms of the line center transmission (t_{ν_o}) .

A second feature of being able to express the integral of the absorption coefficient in terms of the absorption coefficient at line center is that the applicable measurement expression for variation of \mathbf{k}_{ν_0} over the path is

$$t_{m} = \exp\left(-\int k_{\nu_{0}} d\ell\right) \tag{26}$$

where k_{ν_0} is a function of the density and temperature along the path as expressed in Eq. (25). This expression is now amenable to the geometric treatment of Abel inversion for axisymetric flow streams (Ref. 3). That is,

$$\ell_n \frac{1}{\ell_m} = \int_{-L}^{L} k_{\nu_0} d\ell \tag{27}$$

which, for an axisymetric source, can be inverted to (Ref. 3):

$$k_{\nu_0}(r) = -\frac{1}{\pi} \int_r^R \frac{\frac{d}{dy} (\ln t_m^{-1}) dy}{\sqrt{r^2 - y^2}}$$
 (28)

where r is the radius, y is the distance from the axis where the measurement is made, and R is the full radius of the axisymetric source.

2.5 EQUATION FOR THE SPECIES CONCENTRATION

Under conditions of rotational equilibrium, Tatum (Ref. 5) gives expressions for the number density of diatomic molecules in a rotational-vibrational-electronic state satisfying Hund's case "b" as

$$\frac{N_{J''}}{N_{0}} =
\begin{bmatrix}
\frac{2(2S+1) \exp(\int_{e}/\kappa T)}{\sum 2(2S+1) \exp(-\int_{e}/\kappa T)} & \exp[-G(v'')/\kappa T] \\
\frac{\sum 2(2S+1) \exp(-\int_{e}/\kappa T)}{\sum 2(2S+1) \exp(-\int_{e}/\kappa T)} & \exp[-G(v'')/\kappa T] \\
\frac{\sum \exp[-G(v'')/\kappa T]}{\sum 2(2S+1) \exp[-F(J'')/\kappa T]} & \exp[-F(J'')/\kappa T]
\end{bmatrix}$$
(29)

where the new terms used are defined as follows:

S is the electron spin angular momentum quantum number

 $\mathfrak{I}_{\mathbf{P}}$ is the term energy of the electronic state

 $G(v^{"})$ is the vibrational energy of the ν "th vibrational state

F(J'') is the rotational energy of the J''th rotational state

 $N_{\rm O}$ is the total number density of the absorbing species.

The first term in brackets goes to unity for a gas in which only the ground electronic state is populated as is the case in this study. The summations are usually identified as the partition functions for electronic,

$$Q_e = \sum_{0}^{\infty} 2(2S + 1) \exp[-J_n/\kappa T]$$
 (30)

vibration,

$$Q_{v} = \sum_{v=0}^{\infty} \exp\left[-G(v'')/\kappa T\right]$$
 (31)

and rotation,

$$Q_{R} = \sum_{J''=0}^{\infty} (2J''+1) \exp [-F(J'')/\kappa T]$$
 (32)

Substitution of Eq. (29) into Eq. (25) gives

$$\frac{N_o \exp\left[-G(v'')/\kappa T\right]}{Q_v Q_R} = \frac{2J''+1}{2S+1} \exp\left[-F(J'')/\kappa T\right] = \frac{1}{2\sqrt{\pi \ell n 2}} \frac{m_c 2}{e^2} \frac{k_{\nu_o} \Delta \nu_D}{f_{J'J''}}$$
(33)

Rearrangement of terms in Eq. (33) then yields an equation for the total number density of the species:

$$N_{o} = \frac{mc^{2}/e^{2}}{\sqrt{4\pi \ln 2}} \frac{Q_{v}}{\exp\left[-G(v'')/\kappa T\right]} \frac{2S+1}{2J''+1} \frac{Q_{R}}{f_{J'J''}\exp\left[-F(J'')/\kappa T\right]} k_{v_{0}} \Delta v_{D}$$
 (34)

Hence, if a single rotational line of known oscillator strength can be isolated and k_{ν_0} and T can be measured, the number density (N_0) of the absorbing species may be determined.

2.6 EXPRESSION FOR THE OSCILLATOR STRENGTH

The oscillator strength of a rotational line $(f_J'_J'')$ is defined throughout the literature in varying forms. The nomenclature, and hence consistent formulas for the calculation of rotational oscillator strengths, is a much confused subject. The definition of the oscillator strength as used by Schadee (Ref. 6) with the normalization used by Tatum (Ref. 5) will be used in this work. The vibrational oscillator strength $(f_v'_{v''})$ is defined by

$$f_{\mathbf{v}'\mathbf{v}''} = f_{\mathbf{e}\ell} q_{\mathbf{v}'\mathbf{v}''} \tag{35}$$

where $q_{V'V''}$ is the square of the vibrational overlap integral and is known as the Franck-Condon factor. For molecules for which vibrational constants have been accurately measured for several vibrational states, $q_{V'V''}$ can be accurately calculated. Most measurements of the oscillator strength give a value of a particular $f_{V'V''}$ so that f_e can then be found.

The rotational oscillator strength is given by

$$f_{J'J''} = f_{v'v''} \frac{\lambda_{v'v''}}{\lambda_{I'I''}} \frac{\delta_{J'J''}}{(2J''+1)(2)(2S+1)}$$
 (36)

where $\lambda_{V'V''}/\lambda_{J'J''}$ is the ratio of the wavelength at the band head to the wavelength of the particular rotational line of interest. $\delta_{J'J''}/(2J''+1)$ is the normalized Hönl-London Factor for which Earls (Ref. 7) and Kovacs (Ref. 8) give formulas for most transitions encountered. Now, substituting Eq. (36) into Eq. (34) gives

$$N_{o} = \frac{mc^{2}/e^{2}}{\sqrt{4\pi \ell_{n2}}} \frac{2(2S+1)^{2} Q_{v} Q_{r}}{\exp[-G(v'')/\kappa T]} \frac{\lambda_{J'J''}}{\lambda_{v'v''}} \frac{k_{v_{o}} \Delta v_{D}}{S_{J'J''} \exp[-F(J'')/\kappa T]}$$
(37)

which is the general working equation for narrow line absorption.

SECTION III APPLICATION TO THE NO MOLECULE

A considerable amount of literature exists on the energy level structure of the NO molecule. This section is devoted to the definition of the energy levels and transition probabilities of the NO molecule applicable to this study.

3.1 ENERGY LEVELS

The ground electronic energy level of the NO molecule is a doublet Π state, denoted by $X^{'2}\Pi$. All the upper electronic energy levels which have been observed are also doublet states and are denoted by A $^2\Sigma^+$, B $^2\Pi$, C $^2\Sigma^+$, D $^2\Sigma^+$, and E $^2\Sigma^+$ in order of increasing energy. The electronic transitions that have been observed are listed as follows (Ref. 9):

Transition	Designation		
$A^{2}\Sigma^{+} \rightarrow X^{2}\Pi$	γ system		
$B^{2}\Sigma^{+} \rightarrow X^{2}\mathbf{n}$	eta system		
$C^{2}\Sigma^{+} \rightarrow X^{2}\Pi$	δ system		
$D^{2}\Sigma^{+} \rightarrow X^{2}\Pi$	ϵ system		

The energy level diagram showing the electronic energy levels and the transitions to the ground state, producing the γ , β , δ , and ϵ band systems, is shown in Fig. 3.

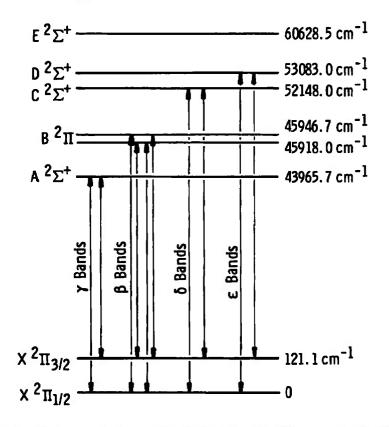

Fig. 3 Electronic Energy Level Diagram of NO Molecule Indicating the Various Band Systems

The applicable equations for determining the various vibrational and rotational energy levels and the vibrational and rotational constants for the NO molecule are given generally by Herzberg (Ref. 10). The majority of work with the NO molecule has dealt with the γ and β systems. Gero and Schmid (Ref. 9) have listed frequencies for

rotational lines in several bands of the γ and β systems and Deezsi (Ref. 11) has published a more comprehensive analysis of the Gero and Schmid data. Additionally, Gero, Schmid, and Von Szily (Ref. 12) give excellent data for the ϵ system and also locate rotational lines for a number of bands in this system. For the present work, the γ band system of NO was chosen because the wavelength region (2200 to 2400 Å) is more easily accessible than for the other, shorter wavelength bands and because the molecular constants are known more accurately.

In general, the equation for the energy levels of a given electronic energy term has the form

$$\mathcal{I} = \mathcal{I}_{e,} + G(v) + F_n(J)$$
 (38)

for which T_e is the ground state electronic energy for that level, G(v) includes the vibrational terms, and $F_n(J)$, the rotational terms.

G(v) has the form,

$$G(v) = \omega_{e}(v + \frac{1}{2}) - \omega_{e}x_{e}(v + \frac{1}{2})^{2} + \omega_{e}y_{e}(v + \frac{1}{2})^{3} + \cdots$$
 (39)

where ω_e , $\omega_e x_e$, and $\omega_e y_e$ are vibrational constants (Ref. 10). Values of \mathcal{I}_e and the vibrational constants for the A $^2\Sigma^+$ and X $^2\Pi$ states are

given in Table I. Note in Table I that ω_e , as given by Gillette and Eyster (Ref. 13), is slightly different for the X $^2\Pi_{1/2}$ and X $^2\Pi_{3/2}$ states.

For doublet states, the term F_n refers to the two electron spin components, $F_1(K-1/2)$ and $F_2(K+1/2)$. The ground electronic energy level (X $^2\Pi$) is intermediate between Hund's cases (a) and (b) (Ref. 13). The Hill and Van Fleck equation for the rotational energy levels for the intermediate case as expressed by Churchhill, Hagstrom, and Landshoff (Ref. 14) is applicable to the X $^2\Pi$ state:

$$F_{n}(J'') = B_{v}[(J'' + \frac{1}{2})^{2} - 1 + (-1)^{n}u] - \begin{cases} D_{v}J''^{4} & n = 1 \\ D_{v}(J'' + 1)^{4} & n = 2 \end{cases}$$
(40)

where

$$B_v = B_e - \alpha_e(v + \frac{1}{2}) \tag{41}$$

$$D_{v} = D_{e} + \beta_{e}(v + \frac{1}{2})$$
 (42)

$$U = [(J'' + \frac{1}{2})^{2} - Y_{v}(1 - Y_{v}/4)]^{\frac{1}{2}}$$
 (43)

$$Y_{v} = A/B_{v} \tag{44}$$

The constants (B_e, α_e , D_e, β_e , and A) for these equations as given in Ref. 13 are included in Table I.

TABLE I MOLECULAR CONSTANTS USED TO CALCULATE SPECTRAL LINE WAVELENGTHS AND INTENSITIES FOR THE NO γ -BANDS

Molecular Constants, cm ⁻¹	x ² n _{1/2}	x ² Π _{3/2}	<u>Α ²Σ</u>
\mathfrak{I}_{e}	62.1	62.1	43965.7

Г			negligible
Α	124.2	124. 2	
Ref.	13	13	15

The upper electronic energy level (A $^2\Sigma^+$) of the γ -system belongs to Hund's case (b) as do all Σ states (Ref. 10). The equations for the rotational energy levels of A $^2\Sigma^+$ states are given by Ref. 10 as

$$F_{1}(J') = B_{v}(J' - \frac{1}{2})(J' + \frac{1}{2}) + \frac{1}{2}\Gamma(J' - \frac{1}{2}) - D_{v}(J' - \frac{1}{2})^{2}(J' - \frac{1}{2})^{2}$$
(45)

$$F_{2}(J') = B_{v}(J' + \frac{1}{2})(J' + \frac{3}{2}) - \frac{1}{2}\Gamma(J' + \frac{3}{2}) - D_{v}(J' + \frac{1}{2})^{2}(J' - \frac{3}{2})^{2}$$
(46)

where $F_1(J')$ refers to the components with J' = K' + 1/2, and $F_2(J')$ refers to the components with J' = K' - 1/2. The splitting constant is Γ and, for NO, may be assumed negligible compared with B_v . The other constants for the A $^2\Sigma^+$ level as derived from rotational analysis by Barrow and Miescher (Ref. 15) are given in Table I.

3.2 SPECTRAL LINES IN THE γ -SYSTEM

The energy of a transition between two levels of a band system is expressed by

$$\nu = \mathcal{J}(\mathbf{v'}, \mathbf{J'}) - \mathcal{J}(\mathbf{v''}, \mathbf{J''}) \tag{47}$$

The selection rules ($\Delta \nu = \nu' - \nu'' = 0$, 1, 2, . . . and $\Delta J = J' - J'' = 0$, ± 1) apply to Eq. (47). By convention, branches of the band for which $\Delta J = 0$ are designated Q branches; for $\Delta J = +1$ they are R branches, and for $\Delta J = -1$ they are P branches. As noted earlier, both electronic energy levels of the system are split into an F_1 and an F_2 level. Because of this, there are then 12 possible transitions which will obey the selection rule. The 12 possible transitions to some J'' level in the v = 0 vibrational level of the $X = 2\pi I_1/2$, 3/2 state are illustrated in Fig. 4. The designation of the various possible transitions shown in Fig. 4 consists of labeling the line as the P, Q, or R branch with subscripts which designate the F_1 or F_2 transition to the appropriate F_1 or F_2 rotational state. That is, $P_{11}(J'')$ refers to a transition from $F_1(J'' - 1)$ to $F_1(J'')$, etc.

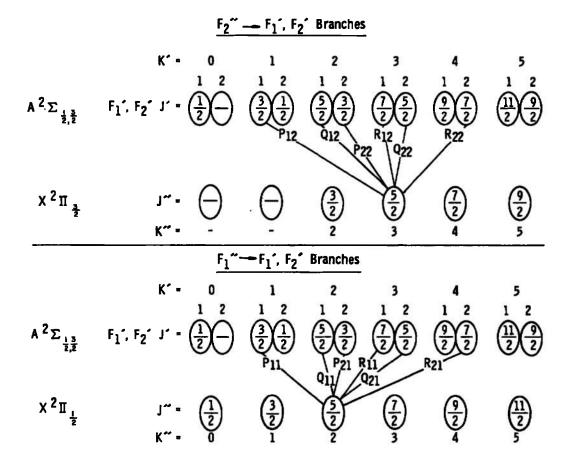

Fig. 4 Allowed Transitions for NO γ -Bands

The spectral lines for the v'=0 vibrational level of the A $^2\Sigma^+$ state to the v''=0 level of the X $^2\Pi$ state were calculated using Eq. (47) and the term formulas for each state given in Eqs. (40), (45), and (46) by means of a computer program written for the IBM 370-155 digital computer. The computer program is described in Appendix II. The calculated lines are shown in Fig. 5 in a way such that the individual lines can be identified. It will be observed that three distinct bandheads appear at 2269.7, 2268.6, and 2263.7 Å. Also, it can be seen that there is much overlapping of lines so that resolution of only a few individual lines is possible.

The computer program described in Appendix II also has the capability to simulate emission spectra that would be obtained from a real spectrometer. The program requires as inputs the oscillator strengths, or transition probabilities of the individual rotational lines of the bands

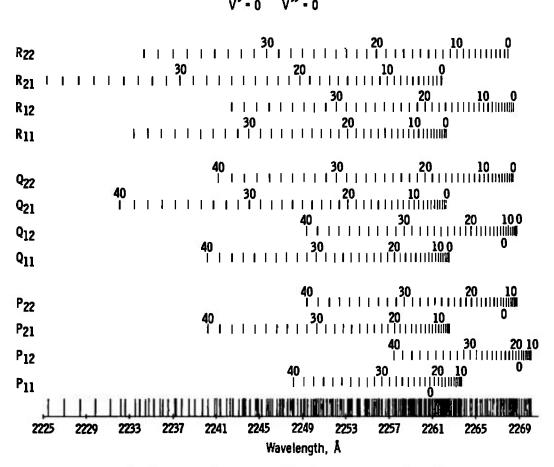

Fig. 5 Computer-Generated Band Structure for the NO (0,0) γ -Band

of interest, the temperature, and the instrument slit function. calculations presented in Appendix II, the oscillator strengths given in the next section for the NO molecule were used. The temperature was chosen as 775°K, which is characteristic of the source of radiation used (see Section IV). The instrument slit function was taken as triangular with a half-width of 0.03 Å, which corresponds to the slit width of the spectrometer used in the work reported here. The simulated spectrum of the (0,0) band of the γ -system appears in Fig. 6 in two plots, one having a slit function of zero half-width and one having the realistic, 0.03 A half-width. The simulated spectrum is also characterized by the three distinct bandheads. Between these bandheads several distinct peaks are found which contain groupings of rotational lines. Some of these distinguishable peaks contain only two or three lines. Several peaks useful for measurements are designated in Fig. 6 as 1. 2, 3, etc., and the line components of the peaks are listed, together with their relative strength, in Table II. At wavelengths shorter than that of the P_{11} bandhead, the lines are badly overlapped and not useful for individual line measurements.

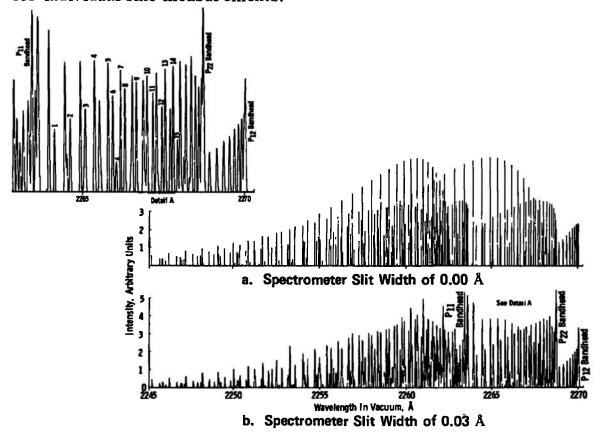

Fig. 6 Computer-Simulated Spectra for the NO (0,0) γ -Band at a Temperature of 775° K

3.3 LINES CHOSEN FOR ABSORPTION MEASUREMENTS

The peaks given in Table II and shown in Fig. 6 which contain strong lines terminating in the same lower rotational state were considered to be the most useful for the absorption measurements. These are the groups containing only $Q_{22}(J^{\,\prime\prime})+R_{12}(J^{\,\prime\prime})$ or $P_{22}(J^{\,\prime\prime})+Q_2(J^{\,\prime\prime})$ lines; in other words, those containing only lines originating from a common lower rotational state. For example, the peak designated as 2 contains $P_{22}(41/2)+Q_{12}(41/2)$ lines and the peak designated as 4 contains only $Q_{22}(25/2)+R_{12}(25/2)$ lines. Only one peak was found which contains a single line, $R_{22}(15/2)$, which is marked X in Fig. 6. Other peaks are overlapped mainly with R_{22} branch lines and the computation of N_0 would be difficult using these.

3.4 OSCILLATOR STRENGTHS FOR THE γ -SYSTEM

The oscillator strength (fj'j'') as defined in Eq. (36) requires knowledge of $f_{v'v''}$ and $\delta_{J'J''}$. Perry-Thorne and Banfield (Ref. 16) have presented the latest results on determination of f_{00} , the

vibrational oscillator strength for the (0,0) band of the system. They give $f_{00} = 3.64 \pm 0.05 \times 10^{-4}$. Spindler, Isaacson, and Wentink (Ref. 17) have calculated values of $q_{\mathbf{V'V''}}$, which are given in Table III, so that any $f_{\mathbf{V'V''}}$ can be determined by use of Eq. (35).

^{*} Taken from Spindler, Isaacson, and Wentink, Ref. 17

$$A^{2}\Sigma - X^{2}\Pi_{3/2}$$

Earls (Ref. 7) has published formulas for the normalized Hönl-London factors for $^2\Sigma$ - $^2\Pi$ transitions, which apply to the γ -system of NO. The expressions are given in Table IV. As noted earlier, the measurement of absorption has to be on pairs of lines originating from the same J´, rather than individual lines. The pairs useful for absorption measurements consist of the P_{22} and Q_{12} lines, and the Q_{22} and Q_{12} lines identified in Table II. Churchill, Hagstrom, and Landshoff

$$\begin{split} R_{22} &= \frac{(2J''+1)^2 + (2J''+1)[Y(Y-4) + (2J''+1)^2]^{-\frac{1}{2}}(4J''^2 + 4J''+1 - 2Y)}{8(J''+1)} \\ Q_{22} &= \frac{(2J''+1)[(4J''^2 + 4J''-1) + \{Y(Y-4) + (2J''+1)^2\}^{-\frac{1}{2}}(8J''^3 + 12J''^2 - 2J''+1 - 2Y)]}{8J''(J''+1)} \\ P_{22} &= \frac{(2J''+1)^2 + (2J''+1)[Y(Y-4) + (2J''+1)^2]^{-\frac{1}{2}}(4J''^2 + 4J''-7 + 2Y)}{8J''(J''+1)} \\ R_{12} &= \frac{(2J''+1)^2 - (2J''+1)[Y(Y-4) + (2J''+1)^2]^{-\frac{1}{2}}(4J''^2 + 4J''-7 + 2Y)}{8J''(J''+1)} \\ Q_{12} &= \frac{(2J''+1)[(4J''^2 + 4J''-1) - \frac{1}{2}Y(Y-4) + (2J''+1)^2]^{-\frac{1}{2}}(4J''^2 + 4J''+1 - 2Y)}{8J''(J''+1)} \\ R_{11} &= \frac{(2J''+1)^2 - (2J''+1)[Y(Y-4) + (2J''+1)^2]^{-\frac{1}{2}}(4J''^2 + 4J''+1 - 2Y)}{8J''(J''+1)} \\ Q_{11} &= \frac{(2J''+1)[(4J''^2 - 4J''-1) + \{Y(Y-4) + (2J''+1)^2\}^{-\frac{1}{2}}(4J''^2 + 4J''-7 + 2Y)]}{8J''(J''+1)} \\ R_{21} &= \frac{(2J''+1)^2 + (2J''+1)[Y(Y-4) + (2J''+1)^2]^{-\frac{1}{2}}(4J''^2 + 4J''+1 - 2Y)}{8J''} \\ R_{21} &= \frac{(2J''+1)^2 - (2J''+1)[Y(Y-4) + (2J''+1)^2]^{-\frac{1}{2}}(4J''^2 + 4J''+1 - 2Y)}{8(J''+1)} \\ R_{21} &= \frac{(2J''+1)^2 - (2J''+1)[Y(Y-4) + (2J''+1)^2]^{-\frac{1}{2}}(4J''^2 + 4J''+1 - 2Y)}{8(J''+1)} \\ R_{21} &= \frac{(2J''+1)^2 - (2J''+1)[Y(Y-4) + (2J''+1)^2]^{-\frac{1}{2}}(4J''^2 + 4J''+1 - 2Y)}{8(J''+1)} \\ R_{21} &= \frac{(2J''+1)[(4J''^2 + 4J''-1) - \{Y(Y-4) + (2J''+1)^2\}^{-\frac{1}{2}}(4J''^2 + 4J''+1 - 2Y)}{8(J''+1)} \\ R_{21} &= \frac{(2J''+1)[(4J''^2 + 4J''-1) - \{Y(Y-4) + (2J''+1)^2\}^{-\frac{1}{2}}(4J''^2 + 4J''+1 - 2Y)}{8(J''+1)} \\ R_{21} &= \frac{(2J''+1)[(4J''^2 + 4J''-1) - \{Y(Y-4) + (2J''+1)^2\}^{-\frac{1}{2}}(4J''^2 + 4J''+1 - 2Y)}{8(J''+1)} \\ R_{21} &= \frac{(2J''+1)^2 - (2J''+1)[Y(Y-4) + (2J''+1)^2]^{-\frac{1}{2}}(4J''^2 + 4J''-1 - 2Y)}{8(J''+1)} \\ R_{21} &= \frac{(2J''+1)^2 - (2J''+1)[Y(Y-4) + (2J''+1)^2]^{-\frac{1}{2}}(4J''^2 + 4J''-1 - 2Y)}{8(J''+1)} \\ R_{21} &= \frac{(2J''+1)^2 - (2J''+1)[Y(Y-4) + (2J''+1)^2]^{-\frac{1}{2}}(4J''^2 + 4J''-1 - 2Y)}{8(J''+1)} \\ R_{21} &= \frac{(2J''+1)^2 - (2J''+1)[Y(Y-4) + (2J''+1)^2]^{-\frac{1}{2}}(4J''^2 + 4J''-1 - 2Y)}{8(J''+1)} \\ R_{21} &= \frac{(2J''+1)^2 - (2J''+1)[Y(Y-4) + (2J''+1)^2]^{-\frac{1}{2}}(4J''^2 + 4J''-1 - 2Y)}{8(J''+1)} \\ R_{21} &= \frac{(2J''+1)^2 - (2J''+1)[Y(Y-4) +$$

*Reference 7

where $Y = A'B_u$

(Ref. 14) have taken into account this overlapping of lines and have expressed the Hönl-London factors, where applicable, as the sum of the Hönl-London factor for each line as follows:

$$\Sigma \delta[Q_{22}(J'') + R_{12}(J'')] = \frac{2J'' + 1}{8J''}[(6J'' - 1) + U(4J''^2 + 4J'' + 1 - 2Y_v]$$
 (48)

$$\Sigma \{ P_{22}(J'') + Q_{12}(J'') \} = \frac{2J'' + 1}{B(J'' + 1)} [(6J'' + 7) - U(4J''^2 + 4J'' + 1 - 2Y_v]$$
 (49)

where J´´ refers to the J-value in the X $^2\Pi_{1/2}$, $_3/_2$ state for a given rotational transition. Here, U has the form

$$U = [Y_v^2 - 4Y_v + (2J'' + 1)^2]^{-1/4}$$
 (50)

where $Y_v = A/B_v$ is the coupling factor. For the NO γ -system, A has a value of 124.2 cm⁻¹. The values of $\Sigma \delta_J \cdots$ for these line pairs for the lines used in this study are also given in Table II.

3.5 MODIFICATION OF SPECTRAL LINE ABSORPTION THEORY FOR MULTIPLETS

Application of Eq. (34) for determining species concentrations requires summing over the two lines of the same wavelength. That is,

$$\sum_{J'o} (\int_{\nu}^{\infty} k_{\nu} d\nu)_{J'J''} = \sqrt{\pi/4 \, \ell n 2} \sum_{J'} (\Delta \nu_{D})_{J'J''}(k_{\nu_{o}})_{J'J''}$$
(51)

For a single line,

$$\int_{0}^{\infty} k_{\nu} d\nu = \frac{\pi e^{2}}{mc^{2}} N_{J}^{\prime\prime} f_{J'J''}$$
 (52)

and for the pair of lines $(Q_{22} + R_{12})$,

$$\sum_{J'} (\int k_{\nu} d_{\nu})_{J'J''} = \frac{\pi e^2}{mc^2} \sum_{J'} N_{J''} f_{J'J''} = \frac{\pi e^2}{mc^2} N_{J''} \sum \delta[Q_{22}(J'') + R_{12}(J'')]$$
 (53)

or, for the pair $P_{22} + Q_{12}$,

$$\sum_{J} (\int k_{\nu} d\nu)_{J'J''} = \frac{\pi e^2}{m c^2} N_{J''} \Sigma \delta[P_{22}(J'') + Q_{12}(J'')]$$

Using Eqs. (45), (46), and (37) and grouping together quantities which explicitly depend on the rotational transitions result in an equation for the concentration:

$$N_{o} = \frac{m_{c}^{2}/e^{2}}{\sqrt{4\pi \ell_{n} 2}} \frac{2(2S+1)^{2} Q_{v} Q_{r}}{\exp\left[-G(v'')/\kappa T\right]} \frac{\lambda_{J'J''}}{\lambda_{v'v''}} \frac{\Delta_{v} D_{J'} \Sigma_{(k_{v_{o}}) J'J''}}{f_{v'v''} (\Sigma_{J'J''}) \exp\left[-F(J''')/\kappa T\right]}$$
(54)

where the quantities $\lambda_{J'J''}$ and $(\Delta\nu_D)_{J'J''}$ are not included under the summations because they are the same for each line in the peak. The definition is made:

$$(\overline{k}_{o})_{\nu_{o}} = \sum_{J'} (k_{\nu_{o}})_{J'J''}$$
 (55)

where $(\bar{k}_0)_{\nu}$ is the measured absorption coefficient. The combination Hönl-London Factor ($\sum_{J'J''}$) is just the sum of the Hönl-London fac-

tors for the pair of lines (Q_{22} + R_{12}) or (P_{22} + Q_{12}), Eqs. (48) and (49).

3.6 FINAL WORKING EQUATIONS

The final step in developing a satisfactory working equation for predicting NO concentrations is the determination of the values of the parameters involved. The quantities in Eq. (54) are given as follows, using cgs units:

$$mc^{2}/e^{2} = 3.555 \times 10^{12} \text{ gm cm}^{2} \text{ sec}^{-2} \text{ esu}^{-2}$$

$$\sqrt{4\pi \ln 2} = 2.953$$

$$2(2S+1)^{2} = 8(S=1/2)$$

$$Q_{v}/\exp\left[-G(v'')/\kappa T\right] \approx 1.000 \qquad (T=293^{\circ}K)$$

$$Q_{r} = \sum_{J=0}^{\infty} (2J+1) \exp\left[-F(J)/\kappa T\right] \approx \kappa T/B_{o} = 122.2 \qquad (T=293^{\circ}K)(\text{Ref. 10})$$

$$\lambda_{J'J''}/\lambda_{v'v''} \approx 1$$

$$\Delta\nu_{D} = 2.228 \times 10^{-6} \lambda^{-1} \text{ cm}^{-1} \qquad (T=293^{\circ}K)$$

$$f_{oo} = 3.64 \times 10^{-4} \quad (\text{Ref. 16})$$

The absorption coefficient at the peak of the absorption line is determined from the relation

$$\overline{k}_{\nu_o} = \frac{1}{L} \ell_n \left(\frac{I_m^o}{I_m} \right)_{\nu_o} \tag{56}$$

where L, the path length through the absorbing gas, is 45.72 cm (for the absorption tube used). The numerical equation for this measurement is thus obtained:

$$N_o = C \ln \left(\frac{I_m^o}{I_m} \right)_{\nu_o}$$
 (57)

where

$$C = \frac{7.22 \times 10^{12}}{\text{L}\lambda \exp\left[-E_{J''/\kappa}T\right]} \begin{cases} s_{J''(Q_{22} + R_{12})} \\ s_{J''(P_{22} + Q_{12})} \end{cases} = \frac{1.59 \times 10^{11}}{\lambda \exp\left[-E_{J''/\kappa}T\right]} \begin{cases} s_{J''(Q_{22} + R_{12})} \\ s_{J''(P_{22} + Q_{12})} \end{cases} (58)$$

where λ is the wavelength at the measured peak in cm. Values of S_J (Q_{22}) , S_J (R_{12}) , S_J (P_{22}) , and S_J (Q_{12}) are given in the tabulations for each line in Appendix II, and their sum is given for each of the peaks used for measurements in Table II. The numerical value of the J (58) at a temperature of 293°K is also given in Table II.

SECTION IV DESCRIPTION OF EXPERIMENT

4.1 APPARATUS

4.1.1 Ultraviolet Spectrometer

A 1-meter Jarrell-Ash grating spectrometer equipped with curved slits was used. The grating had 1180 lines/mm and was blazed at 7500 Å. A Hamamatsu-type R106 photomultiplier tube with S-19 spectral response was used as the detector. The external optics consisted of two fused silica lenses each with an f-number of 4.4. The lenses were placed, as shown in Fig. 7, such that parallel light from the source would pass through the absorbing gas and focus on the slit of

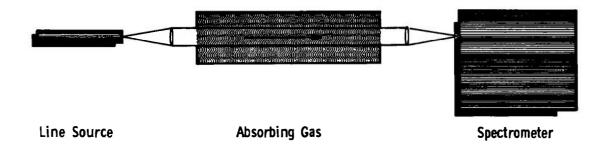

Fig. 7 Diagram of Experimental Apparatus

the spectrometer. A physical slit width of $10\,\mu$ was used for the absorption measurements.

4.1.2 Source of NO Radiation

The source used was the discharge from a small, water-cooled capillary tube containing a mixture of A, N_2 , and O_2 at a pressure of approximately 5mm Hg. A Fluke power supply, operated at 2800 v, was used to maintain a discharge which produced the NO radiation. The discharge was viewed along the axis of the tube. A diagram of the discharge tube is presented in Fig. 8.

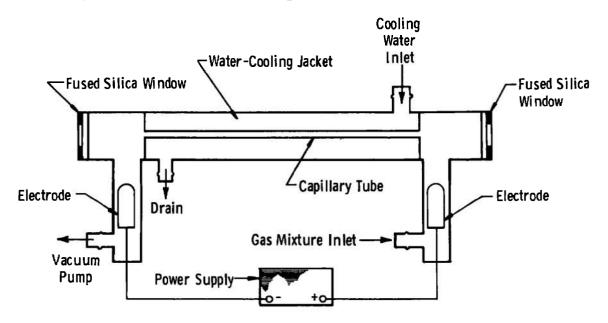

Fig. 8 Diagram of Discharge Tube Used to Produce NO γ-Band Radiation

4.1.3 Absorption Cell

The absorption cell was a stainless steel tube approximately 18 in. in length with an inner diameter of 1-7/8 in. Two 1/4-in.-thick fused silica windows were placed at each end. The cell had four stainless steel valves attached as shown in Fig. 9 to provide for evacuating the cell, bleeding in nitric oxide, bleeding in other gases, and isolating the pressure gage. The system was cleaned and dried before use with the NO. The NO was at room temperature which was $294 \pm 1^{\circ}$ K.

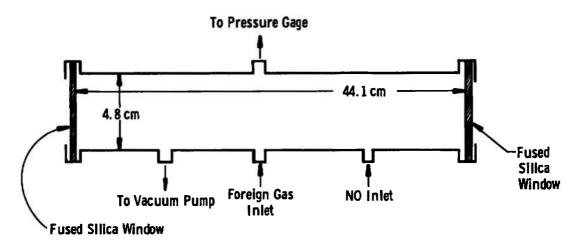

Fig. 9 Diagram of Absorption Cell Used to Contain Samples of NO at Known Pressure and Temperature

4.1.4 Data Recording System

The data recording system is shown in Fig. 10. A Fluke Model 412-B high-voltage power supply was used to provide excitation voltage for the photomultiplier tube. An operating voltage of 800 v was used because it provided the optimum signal-to-noise ratio. The photomultiplier tube signal was fed into a Philbrick Model P-2 operational amplifier having a gain of 100. The signal was recorded on a Mosely stripchart recorder which graphically displayed the spectrum. Linearity of the system was checked using a standard potentiometer and found to be within 0.1 percent. The noise level encountered was found to give the largest instrument uncertainty (approximately ±2 percent) in the measurement.

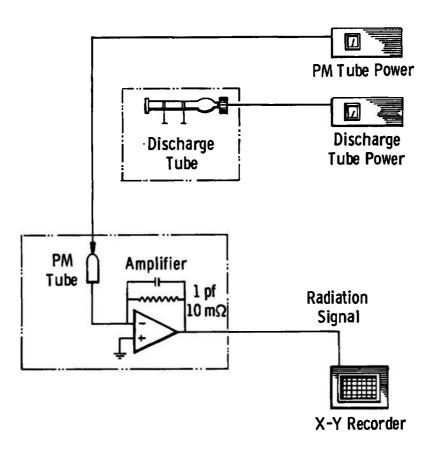

Fig. 10 Diagram of Data Recording System Used with Spectrometer

4.1.5 Gas Property Instruments

Knowledge of the pressure and temperature of the gas in the absorption cell was important so that number densities of NO molecules could be calculated to use for comparison with values obtained from the absorption measurements. A McLeod vacuum gage was used to measure the pressure. The limiting uncertainty of this gage is the readability, which for the range of pressures employed here, is about ± 2.5 percent. The room temperature (assumed equal to the cell temperature) was measured using a mercury thermometer reading in degrees Centigrade. A maximum deviation of one degree from the

observed reading was assumed to be the maximum error. Thus, the maximum uncertainty in the density of the gas in the absorption tube is conservatively estimated to be ±3 percent.

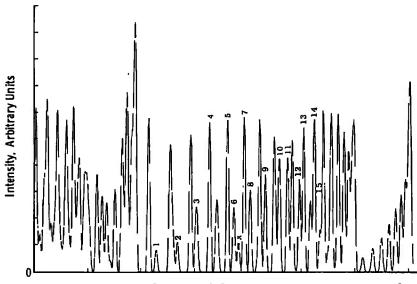

4.2 PERFORMANCE OF NO RADIATION SOURCE

The discharge tube was operated using air, mixtures of NO with argon, and mixtures of N_2 , O_2 , and argon flowing through the tube at various pressures from about 100 microtorr to 5 torr. The most intense and stable radiation of the γ -bands was produced when a 12:3:1 mixture of A: N_2 : O_2 was used at a pressure of 5 torr. The spectrum of the portion of the (0,0) band of interest to this study is shown in Fig. 11. This spectrum was obtained in second order of the 1-meter spectrometer using 10μ slits; under these conditions the resolution was approximately 0.05 Å with a measured equivalent instrument slit width of 0.037 Å. The simulated spectrum calculated for the estimated temperature of the source (373°K) and 0.03 Å instrument slit width is also shown for comparison. Obviously, the calculated line wavelengths and intensities do not exactly correspond to those of the discharge tube, but the comparison is close enough for line identification. The lines previously selected for the absorption measurement are indicated.

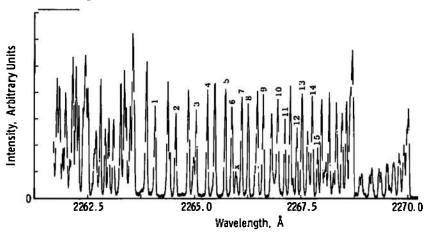

4.3 PROCEDURE FOR ABSORPTION MEASUREMENTS

The absorption tube was first evacuated to a pressure less than 10^{-3} torr and then a base line spectrum covering the wavelength range shown in Fig. 11 was taken. (The base line spectrum was the same with the absorption tube containing air at atmospheric pressure.) Then, the tube was filled with NO at a pressure of about 5 torr, which was found to give absorption of about 90 percent, and the spectral scan, over the wavelength range in Fig. 11, was made. The NO pressure was then reduced by opening the valve to the vacuum pump for a short time, and the spectrum was again obtained. This procedure was repeated over a range of pressures down to 0.018 torr. The pressure in the absorption tube was carefully measured using the McLeod gage for each condition. The tube was then evacuated completely, and a post base line spectra was obtained. In most runs no measurable drift in the intensity of radiation from the discharge tube could be detected.

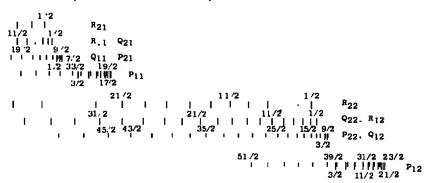

Attempts were also made to test the effect of increased pressure from non-absorbing gases in the tube. However, it was found that only

a. Computer-Simulated Spectra, Slit Width of 0.03 Å

b. Spectrum from Source, Slit Width of 0.03 Å

c. Rotational Line Location

Fig. 11 Portion of (0,0) NO γ-Band Used for Narrow Line

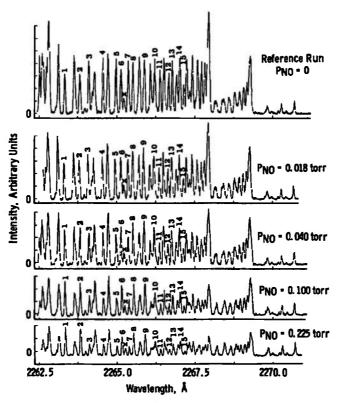

Absorption Measurements

a few torr of air in the tube was sufficient to destroy the NO in a few seconds. Furthermore, with the system used, enough air was introduced when argon or helium was used as the diluent gas to produce the same effect.

SECTION V RESULTS AND DISCUSSION

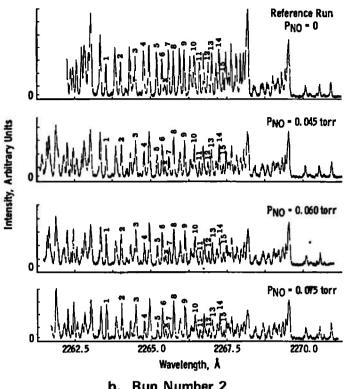

5.1 Results

A set of spectral scans of the NO (0,0) γ -band obtained at different pressures in the absorption cell is shown in Fig. 12. The lines used for the absorption measurements and calculations are indicated. The scans are shown in two sets which were run several days apart.

a. Run Number 1

Fig. 12 Experimental Data from Absorption Measurements of NO γ -Band Radiation Passing through a Low-Pressure Absorption Tube Containing NO

b. Run Number 2 Fig. 12 Concluded

The calculated density of NO as a function of the transmission $(I_m/I_m^O)_{\nu_O}$ using Eqs. (57) and (58) with the data from Table II is shown in Fig. 13 for several spectral lines. Also shown in Fig. 13 is the transmission at different densities calculated from the data in Fig. 12, and the transmission at line center for each of these data points obtained using the method of Appendix I. Agreement between theory and experiment is considered good (after the conversion from measured transmission to line center transmission is made) for those peaks containing $Q_{22} + R_{12}$ lines from a common J´´ state when the transmission is greater than about 12 percent. For some reason (possibly overlap from adjacent lines), the $P_{22} + Q_{12}$ lines and the single R_{22} line give poor comparison to the theoretical curve. No consistent trend in the deviation from the theoretical for the $Q_{22} + R_{22}$ lines could be detected, and the deviations from the theoretical curve appear to be no larger than 20 percent.

Equations (57) and (58) may also be written in the form

$$\ell_n \frac{\ell_n \, I_m^0 / I_m}{S_{J''}(Q_{22} + R_{12})} = \ell_n \frac{\lambda}{1.55 \times 10^{-11}} - \frac{E_{J''}}{\kappa T}$$
 (59)

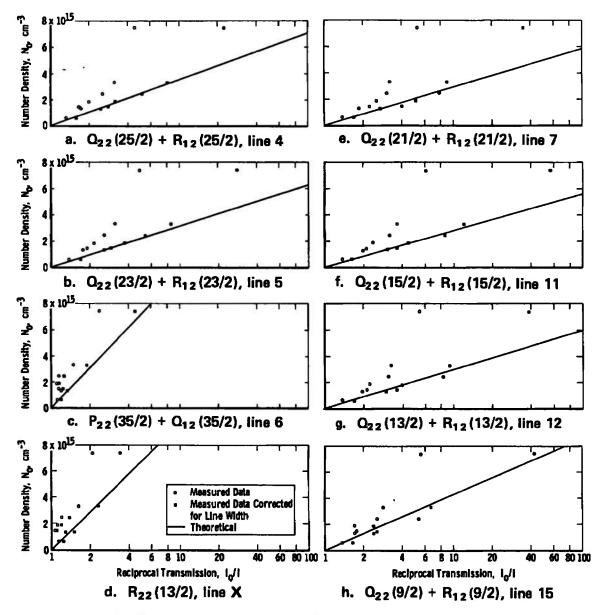

Fig. 13 Theoretical and Experimental Transmission of Several NO (0,0) γ -Band Lines through NO Gas at Various Pressures

where only the $Q_{22}+R_{12}$ lines have been included. When the left-hand side of the equation is plotted versus Ej", a straight line should result having a slope of $1/\kappa T$, and thus the rotational temperature can be determined. Such a plot for the data of Fig. 13 and using the properties of Table II is given in Fig. 14. The least-squares straight line shown gives a temperature of 293°K, that is, room temperature. This result serves as a check on the method and also shows that the absorption data can be used for temperature measurement.

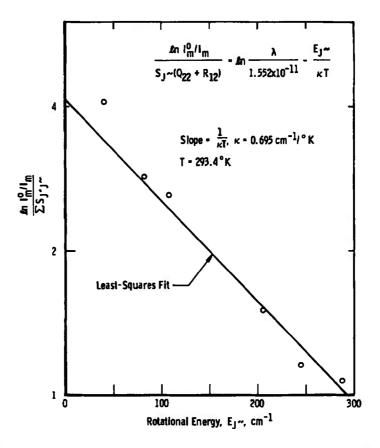

Fig. 14 Boltzmann Plot of Rotational Line Transmission for Determination of Rotational Temperature

5.2 Discussion of the Method

5.2.1 Validity of the Derived Working Equation

The work reported above serves to assemble the necessary analysis and molecular data for the use of measurement of the absorption coefficient of rotational lines in the γ -system of NO to determine concentration of the NO molecule. Furthermore, the experimental measurement serves to validate the accuracy of the derived working equations, Eqs. (57) and (58). This is gratifying for the following reasons. Derivation of an accurate expression such as Eq. (54) is tedious because of the bookkeeping necessary to keep track of the various statistical weights and partition junctions for rotational states of diatomic molecules. Moreover, the state of normalization of expressions for Hönl-London factors such as those expressed in Table IV (Ref. 7) is always suspect.

Expression of the Boltzmann population densities and line strengths must also be done in a systematic way. The approach taken by Tatum (Ref. 5) was strictly adhered to in this derivation, with apparent success.

5.2.2 Use of the Correction for Non-Narrow Line Source

The method for converting the measured transmission to line center transmission, when the source line width is about the same magnitude as the absorber line width, was of great use in this work. The ratio:

$$a = \frac{\Delta\lambda (\text{sour ce})}{\Delta\lambda (\text{absor ber})}$$
 (60)

may be expressed as

$$a = \sqrt{\frac{T \text{ (source)}}{T \text{ (absorber)}}}$$
 (61)

when Doppler broadening can be considered the principal broadening mechanism. In the experimental situation encountered in this report, the source temperature was estimated as 393°K while the temperature of the absorbing gas was room temperature (293°K). Then, a = 1.16, the value used in the correction. If the source temperature estimate is wrong by ±20°K, the correction curve shown in Appendix I will not change by an appreciable amount. The theoretical accuracy of the correction cannot be stated with any degree of confidence because of the complexity of the derivation (see Ref. 1). However, as shown by the data in Fig. 13, the correction works rather well.

As the temperature of the absorber gas increases to that typical of combustion gas streams, such as jet engine exhausts (one to three thousand degrees Kelvin), "a" becomes small, and the correction becomes less important. However, for use in the detection of NO in the atmosphere, the correction is necessary.

5.2.3 Non-Uniform Absorbing Media

The transmittance depends on the temperature and concentration along the absorbing path. If these are constant along the path, then Eq. (54) is directly applicable for determination of either concentration or temperature. If either temperature or concentration is variable along

the path, then additional knowledge is necessary to deduce profiles from measured transmittances. If the temperature profile is known from some other measurement, then the total number of absorbing molecules along the path can be determined by breaking the path up into any number of zones of constant temperature. If the absorbing gas stream is axisymetric, then the radial profile of both concentration and temperature can be determined by use of the Abel integral inversion technique as reported by Seiber (Ref. 3) and discussed previously. This method requires that several measurements be made through a plane of the axisymetric flow.

5.2.4 Range of Application

The concentration range is limited because of experimental constraints to values of I_0/I_m from about 1.05 to 10. This, in turn, limits the range in the product $k_0\ell$ from about 0.07 to 2.3. Since k_0 varies as N_0 , the range of N_0 can be controlled somewhat by controlling the path length (ℓ). Some control over the range is also afforded by choice of the rotational line used, as illustrated in the curves in Fig. 13. For example, the $P_{22}(35/2) + Q_{12}(35/2)$ line can theoretically be used for values of N_0 up to about 10^{16} cm⁻³ at room temperature, while the Q_{22} , R_{12} lines are only useful up to about 3×10^{15} cm⁻³. The lower limit for all the useful lines in the (0,0) band of the NO γ -system is about 10^{14} cm⁻³. If the temperature of the absorber is increased to 2000° K then the upper limit is reduced to about 10^{15} cm⁻³ for the P_{22} , Q_{22} lines but does not change appreciably for the Q_{22} , Q_{22} lines.

The overall range of NO which can be measured using the absorption technique is mainly controlled by the value

$$f_{v'v''} \exp\left[-G(v'')/\kappa T\right]/\sum_{v''} \exp\left[-G(v'')/\kappa T\right]$$
 (62)

in Eq. (54). For v''=0, the exponentials reduce to unity at room temperature so that, for the (0,0) band, this expression is just f_{00} . However, for v''=1, v'=0, the expression becomes

$$\frac{f_{o1} \exp \left[-G(1)/\kappa T\right]}{\sum \exp \left[-G(v'')/\kappa T\right]} = \frac{q_{o1}}{q_{oo}} f_{oo} \frac{\exp \left[-2828/(0.695)(293)\right]}{\exp \left[-950/(0.695)(293)\right]}$$
(63)

Values of the Franck-Condon factors are given in Ref. 17 and are listed in Table III. The expression has a value of 1.62 x 10^{-4} f₀₀ and therefore, for the (0,1) band,

$$N_{o} = 4.45 \times 10^{16} \frac{\ln (I_{o}/I_{m})}{\bar{L}} \frac{1}{\lambda \exp [-E_{I''}/\kappa T]S_{I''}}$$
 (64)

The measurable range of N_0 for lines in the (0,1) band is thus from about 5×10^{17} to about 10^{19} cm⁻³. Measurements in this range using the (0,1) band were made previously by Litton (Ref. 18).

5.2.5 Validity of Oscillator Strengths

After careful evaluation of the experiments reported in the literature, the value of f_{00} selected for this study was that of Perry-Thorne and Banfield (Ref. 16), which was determined by the Hook interferometric technique. Hasson, Farmer, and Nichols (Ref. 19) have recently published new values obtained by a modification of this technique and have reviewed the values obtained by several investigators using several methods. Their concensus is that the value lies near 4.1 x 10^{-4} . The deviation of this value from that of Ref. 16 is ± 13 percent. The experiment carried out in this study would have detected consistent deviations greater than about 5 percent. Thus, it is concluded that the Perry-Thorne and Banfield value was not a bad choice, and that other published values may be somewhat high.

SECTION VI CONCLUSIONS

The following conclusions can be reached from this study:

- The theoretical approach to spectral line absorption, when details are carefully attended to, leads to accurate expression for the number density of NO in terms of the measured line transmission, molecular properties, and the gas temperature.
- 2. The oscillator strength reported in the literature by Perry-Thorne and Banfield (Ref. 16) appears to be correct.
- 3. Application of the correction of measured transmission to transmission at line center, using the method of Mitchel and Zemansky (Ref. 1), is necessary when the temperature of the absorbing gas is not much greater than that of the source, and appears adequate for absorption values not exceeding about 50 percent.

4. The method, as applied here, using the (0,0) γ -band leads to determinations of NO number density with an uncertainty not exceeding 20 percent for values of N_0 between about 10^{14} and 3×10^{15} cm⁻³, at path lengths of about 50 cm. The range can be adjusted somewhat by choice of spectral line used or the path length. For larger densities, the (0,1), (0,2), etc., bands may also be used.

- II. DESCRIPTION OF COMPUTER SIMULATION AND BAND SPECTRA

APPENDIX I

DESCRIPTION OF METHOD FOR CONVERSION OF MEASURED LINE TRANSMISSION TO LINE CENTER TRANSMISSION FOR NON-NARROW LINE SOURCES

The accurate measurement of the absorption coefficient at line center (k_{ν}) is the key to the "narrow line absorption method." The ideal case is one in which the line source has a width that is much narrower than the absorption line. In the practical case, this condition is rarely met, but, fortunately, a correction can be made to the measured transmission that adequately compensates for the experimental condition. The basic requirements for the correction are given by Mitchell and Zemansky (Ref. 1).

The general expression for the measured transmission (tm) is

$$t_{\rm m} = \frac{\int I_{\nu} d\nu}{\int I_{\nu}^{\rm o} d\nu} \tag{I-1}$$

where I_{ν}^{O} is the incident spectral intensity and I_{ν} is the transmitted spectral intensity at a frequency (ν), I_{ν} is related to I_{ν}^{O} by

$$I_{\nu} = I_{\nu}^{0} \exp\left(-k_{\nu}\ell\right) \tag{I-2}$$

If the absorption line is subject only to Doppler broadening, then

$$k_{\nu} = k_{\nu_0} \exp \left\{ -\left[2 \frac{(\nu - \nu_0)}{\Delta \nu_D} \sqrt{\ell_{n} 2} \right]^2 \right\} = k_{\nu_0} \exp (-W^2)$$
 (I-3)

where k_{ν_0} is the absorption coefficient at the line center frequency (ν_0), $\Delta\nu_D$ is the width of the Doppler profile at half intensity, and W has the obvious definition. Thus

$$I_{\nu} = I_{\nu}^{\circ} \exp\left[-k_{\nu} \ell \exp(-W^2)\right]$$
 (I-4)

Now, let

then

$$I_{\nu}^{\circ} = I_{\nu_{0}}^{\circ} \exp\left[-(W/a)^{2}\right]$$
 (I-5)

Substituting Eqs. (I-4) and (I-5) into Eq. (I-1) gives the transmission:

$$t_{m} = \frac{\int_{-\infty}^{\infty} \exp[-(W/a)^{2}] \exp[-W/a] \mathcal{L} dW}{\int_{-\infty}^{\infty} \exp[-(W/a)^{2}] dW}$$
 (I-6)

As shown in Ref. 1, this expression can be expanded in a series as follows:

$$t_{m} = 1 - \frac{k_{\nu_{0}} \ell}{\sqrt{1 + a^{2}}} + \frac{(k_{\nu_{0}} \ell)^{2}}{2!\sqrt{1 + 2a^{2}}} + \cdots + (-1)^{n-1} \frac{(k_{\nu_{0}} \ell)^{n}}{n!\sqrt{1 + na^{2}}} + \cdots$$
 (I-7)

Equation (I-6), or (I-7), expresses the actual, measured value of the transmission (t_m) in terms of the true value of the transmission at the line center ($k_{\nu_0} \ell = \ell n (I_{\nu_0} / I_{\nu_0}^0) = \ell n t_{\nu_0}$) through the parameter (a). For Doppler broadening,

$$\Delta \nu_{\rm D} = 2 \nu_{\rm o} \sqrt{\frac{2\kappa T \ln 2}{Mc^2}} \tag{I-8}$$

where κ is Boltzmann's constant, M is the molecular weight, c is the velocity of light, and T is the temperature, so that

$$a = \sqrt{\frac{T(source)}{T(absorber)}}$$
 (I-9)

Equation (I-6) can be evaluated numerically to give $t_{\mathbf{m}}$ as a function of $\nu_{\mathbf{0}}$ with "a" as a parameter.

In Fig. (I-1) is plotted $t_{\rm m}^{-1}$ versus $t_{\nu_0}^{-1}$ for several values of "a" ranging from 0 to 1.5. The particular value of a = 1.16 applies to the condition of a 110°C source temperature being transmitted through a room temperature (20°C) absorber. For example, at this condition, a measured value of $t_{\rm m}^{-1}$ = 2 when corrected for a = 1.16 becomes t_{ν_0} = 3.15; that is, the measured 50-percent transmission would be 32-percent transmission if a = 0, the condition of a very narrow emission line.

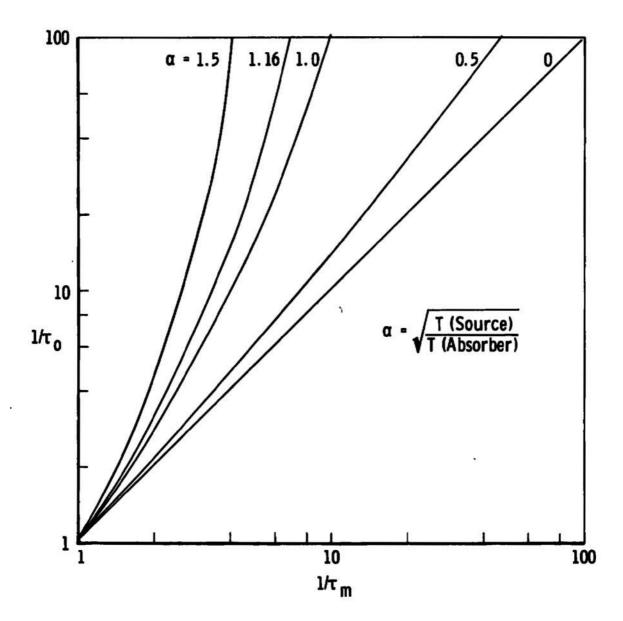

Fig. I-1 Conversion of Measured Transmission at Line Center for Doppler Broadened Lines (Ref. 1)

APPENDIX II DESCRIPTION OF COMPUTER SIMULATION AND BAND SPECTRA

A computer program and plotting procedure for computing and simulating the rotational structure of vibrational bands in electronic transitions of diatomic molecules is described in this appendix. The program proceeds to compute and print out the energy levels in cm⁻¹ for the upper and lower states selected for the transition, using the standard equations (Ref. 10):

Upper
$$\mathcal{I}' = \mathcal{I}_{e'} + G'(v') + F_{n'}(J')$$
 (II-1)

Lower
$$\mathcal{I}'' = \mathcal{I}_e'' + \mathcal{G}''(v'') + \mathcal{F}_n''(J'')$$
 (II-2)

where

 \mathcal{I} - total energy of the state

 \mathcal{I}_{e} - electronic state energy at v = 0, J = 0

G(v) - vibrational energy of the v = 0, 1, 2, 3 · · · vibrational state

F_n(J) - rotational energy of the J = 0, 1, 2, · · · rotational state for multiplet states, n = 1, 2, 3, · · · so that I has a different value for each multiplet

The standard equation is used throughout for the vibrational energy:

$$G(v) = \omega_e(v + 1/2) - \omega_e x_e(v + 1/2)^2 + \omega_e y_e(v + 1/2)^2, v = 0, 1, 2 \cdot \cdot \cdot \quad (II-3)$$

The quantities ω_e , $\omega_e x_e$, and $\omega_e y_e$ are vibrational constants of the molecule which may generally be found in Herzberg (Ref. 10) or in the published literature. In special cases, the constants may be different for the different components of a multiplet.

The expression (F_n) for the rotational energy term is usually different for each molecule and is considered as an input to the program. All Σ states belong to Hund's coupling case "b" (Ref. 10), and for $^2\Sigma$ states (the upper state for the NO γ -band system is a $^2\Sigma$ state), the equations are

$$F_{1}(J') = B_{v}(J'+1/2)(J'-1/2) + 1/2\Gamma(J'-1/2) - D_{v}(J'+1/2)^{2}(J'-1/2)^{2}$$

$$J' = 1/2, 3/2, 5/2, \dots$$
(II-4a)

$$F_2(J') = B_v(J' + 1/2)(J' + 3/2) - 1/2\Gamma(J' + 3/2) - D_v(J' + 1/2)^2(J' + 3/2)^2$$

$$J' = 1/2, 3/2, 5/2, \dots$$
(II-4b)

The rotational constants B_v and D_v depend on v and are given by

$$B_v = B_e - \alpha_e(v + 1/2)$$
 (II-5)

$$D_v = D_e + \beta_e(v + 1/2)$$
 (II-6)

with B_e , α_e , D_e , and β_e constant. The constant Γ is known as the spin splitting constant and is usually very small for Σ states. The lower rotational state of NO is a $^2\Pi$ state intermediate between Hund's cases "a" and "b" and for such a case the Hill and van Fleck formula was derived (Ref. 10). It is expressed as follows:

$$F_1(J'') = B_v[(J'' + 1/2)^2 - 1 - u] - D_vJ''^4$$
 (II-7a)

$$F_2(J'') = B_v[(J'' + 1/2)^2 - 1 + u] - D_v(J'' + 1)^4$$
 (II-7b)

where $B_{\mathbf{V}}$ and $D_{\mathbf{V}}$ are expressed as in Eqs. (II-5) and (II-6) and u is given by

$$u = [(J'' + 1/2)^2 - Y_v(1 - Y_v/4)]^{1/2}$$
 (II-8)

with $Y_v = A/B_v$, A being the coupling constant.

The constants for NO used in these calculations were the most accurate available; for the X $^2\Pi$ state, the values of Gillette and Eyster (Ref. 13) were used, and for the A $^2\Sigma$ state, those obtained by Barrow and Miescher (Ref. 15) were used. The term values are given for J values out to 81/2 for the v = 0 and v = 1 vibrational states in Table II-1.

The spectral line computations are made in the program from the equation:

$$\nu = \frac{1}{\lambda} = \Im' - \Im'' \text{ cm}^{-1}$$

$$= (\Im_{e}' - \Im_{e}'') + [G(v') - G(v'')] + [F_{n}(J') - F_{n}(J'')] \qquad (II-9)$$

$$\Delta v = 0, \pm 1, \pm 2, \cdots$$

$$\Delta J = \begin{cases} +1 & R \text{ branches} \\ 0 & Q \text{ branches} \\ -1 & P \text{ branches} \end{cases}$$

Each kind of transition, $^2\Sigma \rightarrow ^2\Pi$, $^3\Sigma \rightarrow ^3\Pi$, $^1\Delta \rightarrow ^1\Sigma$, etc., has its own peruliarities (Q formed P branches, R formed Q branches, etc.) which are described adequately by Herzberg (Ref. 10). Suffice it to say here that the computer programming problem in computing these spectral line wavelengths is mainly one of tedious bookkeeping. For the NO molecule, all 12 possible doublet-to-doublet transitions are present, and the details of the structure are explained in the text of this report. The computed spectra (ν and λ) are given in Table II-2 for all the branches of the (0,0) band.

Two methods of plotting the spectra are available. First, the lines of the different branches of a single band may be separated and then combined as shown in Fig. 5 of the text. This plot is similar to what would be observed on a photographic plate from a spectrograph and permits identification of the individual lines. It is of especial value in determining which lines overlap in a spectrum of given resolving power.

In the second method of plotting, an attempt is made to simulate the spectrum that would be produced by a monochrometer. For this purpose, it is also necessary to compute the intensities of the lines. Most sources produce spectra that exhibit near-Boltzmann-like distributions in rotational line distribution with some less-Boltzmann-like vibrational distributions. For purposes of comparison of computed spectra to real spectra, the assumption of a Boltzmann distribution was made. Then, the emission coefficient ($\epsilon_{\mathbf{J}',\mathbf{J}''}$) of the rotational lines within a band are given by

$$\epsilon_{J'J''} = \frac{hc}{\lambda_{J'J''}} A_{n'n''} q_{v'v''} \frac{\delta_{J'J''}}{(2J'+1)g_{n'}}$$
 (II-10)

where

h = Plank's constant, erg sec

c = Velocity of light, cm/sec

 $^{\lambda}J'J'' =$ wavelength of the spectral line produced by the J' - J'' transition, cm

qu'e" = vibrational over lap integral, or Franck-Condon factor (Ref. 10)

 $\delta_{1'1''}$ = rotational strength, or Hönl-London factor for the rotational transition

2S'+1 = statistical weight of the rotational level

N(n', v', J') = number of molecules occupying the J'rotational state in the v'vibrational level of the n'electronic level

For the Boltzmann distribution, the distribution of vibrational and rotational states within the electronic level is given by

$$N(v', J') = N_0 \frac{\exp\left[-G(v')/\kappa T\right]}{\sum_{v'} \exp\left[-G(v')/\kappa T\right]} \times \frac{g_{J'} \exp\left[(-F_n J')/\kappa T\right]}{\sum_{J'} g_{J'} \exp\left[(-F_n G v')/\kappa T\right]}$$
(II-11)

where:

 N_o = total number of molecules κ = Boltzmann's constant, 0.6952 cm⁻¹/°K T = Temperature (H-12) g_J = statistical weight of the rotational state; usually g_J = (2S + 1)(2J'' + 1), Σ states 2(2S + 1)(2J' + 1), other states

(See Ref. 5 for exceptions to this expression.) The computation of the intensity of each line proceeds from Eqs. (II-10) and (II-11). The values of $A_{n'n'}$ and $q_{v'v'}$ are found in the literature for most bands. If the interest is only in the rotational distribution with a band, then the product of all the terms not explicitly dependent on J' may be set to unity. This is done in the present report. Or, the entire equation may be utilized if all the terms are known.

The quantity $\delta_{J'J''}$ must be given special attention, since, for other than singlet transitions, it may become quite involved. Expressions for $\delta_{J'J''}$ like F(J) are usually different for each case computed and depend on the electronic momentum states and the degree of coupling of orbital, spin, and rotational angular momentum as expressed by Hund's coupling cases. For the ${}^2\Sigma \rightarrow {}^2\Pi$ transition with the ${}^2\Pi$ state intermediate between Hund's cases "a" and "b" (the case for NO γ -bands), the formulas of Table IV are used. In the computer program the expression for J'J'' is input for each spectra to be calculated.

The simulation of the monochrometer as usually recorded on a strip chart recorder is accomplished by numerical integration of the components of each line as determined by the wavelength, the line strength, the line width, and the monochrometer bandpass. The line width consideration will not be a part of this Appendix because the line broadening (natural, pressure, Doppler, Stark) encountered in this study are much smaller than the bandpass of the instrument used. However, the computer program is capable of handling these phenomena. The instrument band pass is taken here as a triangular function:

Ċ

$$\int \epsilon_{\lambda} d\lambda \epsilon = \epsilon_{0} \begin{cases}
\frac{\Delta \lambda - (\lambda_{0} - \lambda)}{\Delta \lambda}, & \lambda < \lambda_{0}; 0, \lambda < \lambda_{0} - \Delta \lambda \\
\frac{\Delta \lambda - (\lambda - \lambda_{0})}{\Delta \lambda}, & \lambda > \lambda_{0}; 0, \lambda > \lambda_{0} + \Delta \lambda
\end{cases}$$
(II-13)

where ϵ_0 is the emission coefficient as computed in Eq. (II-10), λ_0 is the wavelength at the center of the line, and $\Delta\lambda$ is the half-width of the triangular bandpass. The equivalent half-width in wavelength units is given by the product of the reciprocal dispersion (Å/mm) of the instrument and the actual instrument slit width in mm (assuming entrance and exit slit widths are equal as in the case for all work reported here). The computer is then given a temperature, $\Delta\lambda$, the molecule constants, and a wavelength plotting scale (Å per inch of recording paper) which is the same as the experimental scale. Simulated spectra for the (0,0) band of the NO γ -system then appear as in Fig. 6. If the overlap of lines within an apparent peak is suspected, then $\Delta\lambda$ may be set equal to zero, and the spectrum as plotted in Fig. 6 results.

This computer program is of great utility in studies of the nature of this report, and line identification from experimental data is almost impossible without it. The program is written for the IBM-370/155 computer with a Cal-Comp plotter.

determination of the concentration of the absorption of individual spectra A in the NO (0,0) γ-band are present the derivation is accurate, that pulstrengths are adequate, and that meaninger than the derivation of the relative line was made. The density range of use of the corrections for the relative line was made. The density range of use of the total correction of the lengths usually the sting (10 to 100 cm). Extension of the uniform concentration and temperature	of nitric al lines lited. It is blished values as a surements of second terms of the rangapplication	oxide for ying between shown end of number ossible wource and is din combined in to medi	measurement of yeen 2270 and 2260 experimentally that escillator er densities with yhen proper are from about 1014 to oustion system eger concentrations
